

HR Analytics Dashboard

Problem Statement

Employee attrition is a major challenge for organizations because high employee turnover can increase recruitment costs, reduce productivity, and affect workforce stability. However, identifying which employee groups experience higher attrition can be difficult when HR data contains many employee, job, compensation, and demographic attributes.

This project aims to analyze employee data using Power BI to identify patterns and factors associated with employee attrition. The analysis focuses on variables such as age, salary, overtime, job role, department, education, job satisfaction, gender, and years at the company.

Project Goals

- Measure the overall employee attrition rate.
- Identify employee segments with higher observed attrition.
- Understand how overtime and compensation relate to attrition.
- Identify job roles and departments with higher turnover.
- Analyze demographic and educational patterns.
- Examine the relationship between job satisfaction, tenure, and attrition.
- Provide data-driven insights that can support employee retention strategies.

Expected Business Outcome

The analysis is intended to help HR teams and management understand where employee attrition is concentrated and identify areas that may require further investigation. The resulting Power BI dashboard provides an interactive view of key workforce metrics and enables users to explore attrition across different employee segments.

Analytical Note

The project identifies associations within the available HR data; it does not establish that any individual factor directly causes employee attrition. Business decisions should therefore be supported by additional information such as employee surveys, exit interviews, workload data, and compensation benchmarks.
